

THE REGIONAL DISTRICT OF EAST KOOTENAY
MOSQUITO CONTROL PROGRAM
WASA/TA TA CREEK/SKOOKUMCHUCK MOSQUITO CONTROL EXTENDED SERVICE
AREA

SEASON END REPORT
NOVEMBER 2014

PROGRAM STAFF:
Mark Vaandering Project Manager
Kendra Lewis Program Coordinator/Mosquito Control Technician

CONTAINING:
Summary of 2014 Season Activities

Morrow BioScience Ltd.

SUMMARY OF ACTIVITIES

As with the previous three seasons, 2014 was busy one for mosquito control and the Wasa, Ta Ta Creek and Skookumchuck area. While the snow levels in the basins feeding this floodplain were higher than average, weather conditions were favorable to a relatively slow melt and lower than expected river levels.

The first treatment took place on May 23. Ground treatments continued through July 24.

On May 25 the river peaked at 3.98m (as measured at station 08NG065 – Kootenay River at Fort Steele). This high water resulted in an increase in larval activity of a very large area. At this point ground crews could no longer access many of the areas requiring treatment and a helicopter was brought in to conduct a large-scale treatment.

The first aerial treatment took place on June 3 as a result of the highest peak of the season.

The water levels were sustained at a relatively high level from late May until early July. This sustained water level resulted in increased seepage areas. A second aerial was conducted on June 25 to address these concerns.

This season a total of 1,189 hectares were treated, well above the 700 hectares included in the base contract.

Morrow BioScience Ltd (MBL) employees received no complaint calls concerning adult mosquito annoyance in this program this season.

SNOW AND RIVER LEVELS

Snow accumulations throughout the East Kootenay region (fig. 1-3) began this season above average. The melt through the end of May was relatively quick, resulting in a significant peak on May 25. The river level was maintained at a level that resulted in water table pressure and resulting seepage water through much of June. Most of the low and mid-elevation snow came out during May, reducing the risk of a freshet induced flood event.

By the end of June all of the significant snow was out of the system, all but eliminating the risk of subsequent flooding. (fig. 4)

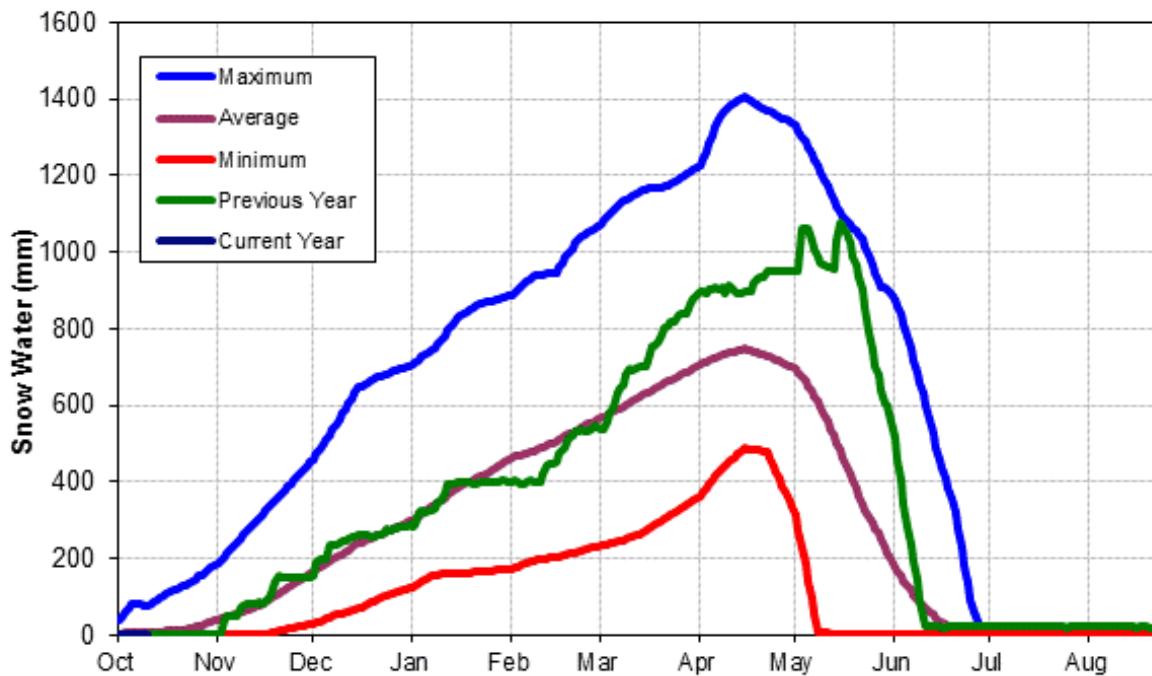

Figure 1. Snow pillow for Morrissey Ridge (2C09Q). The green line represents the accumulated snow levels for the 2014 season.

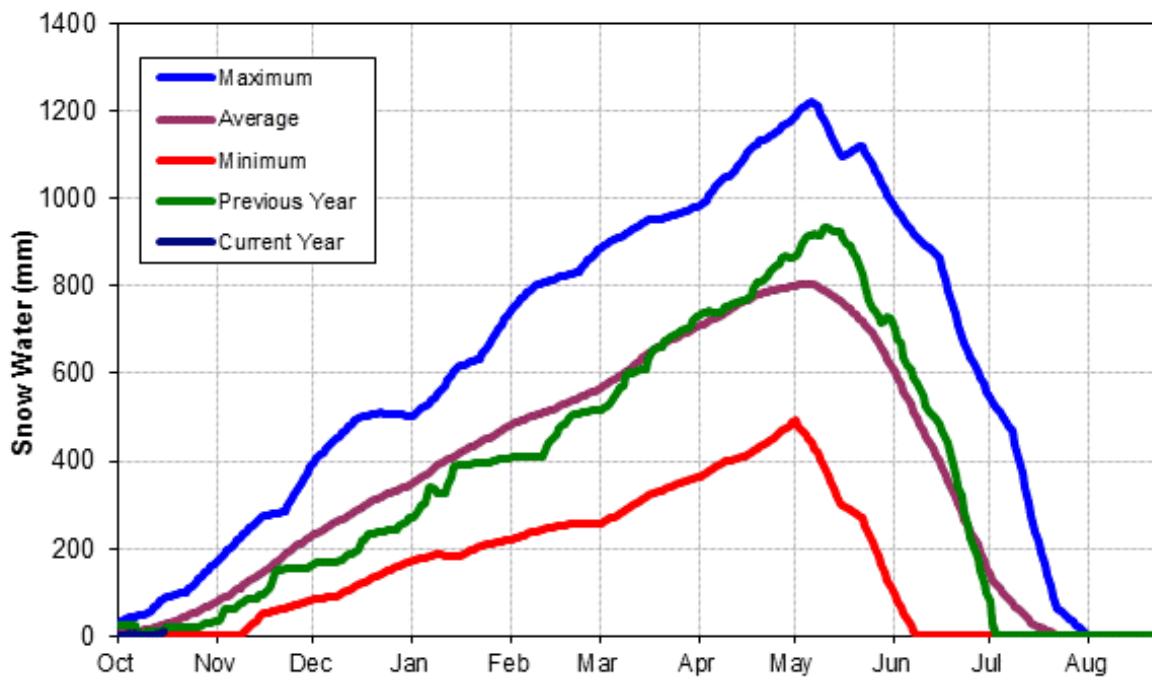

Figure 2. Snow pillow for Floe Lake (2C14P). The green line represents the accumulated snow levels for the 2014 season.

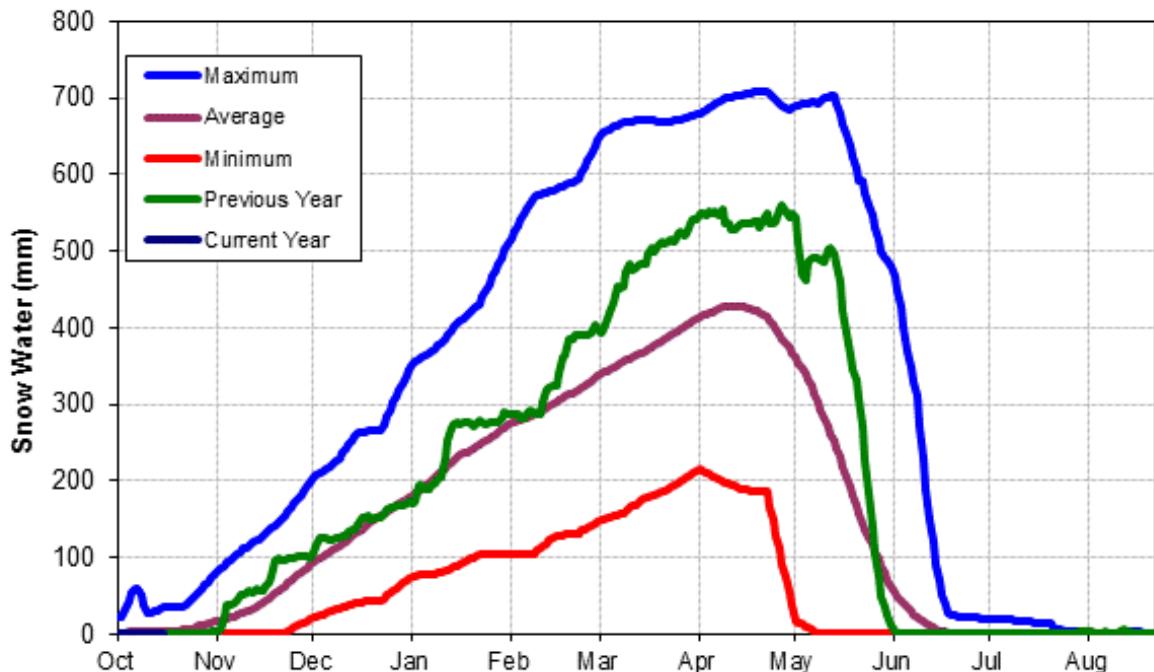

Figure 3. Snow pillow for Moyie Mountain (2C10P). The Green line represents the accumulated snow levels for the 2014 season.

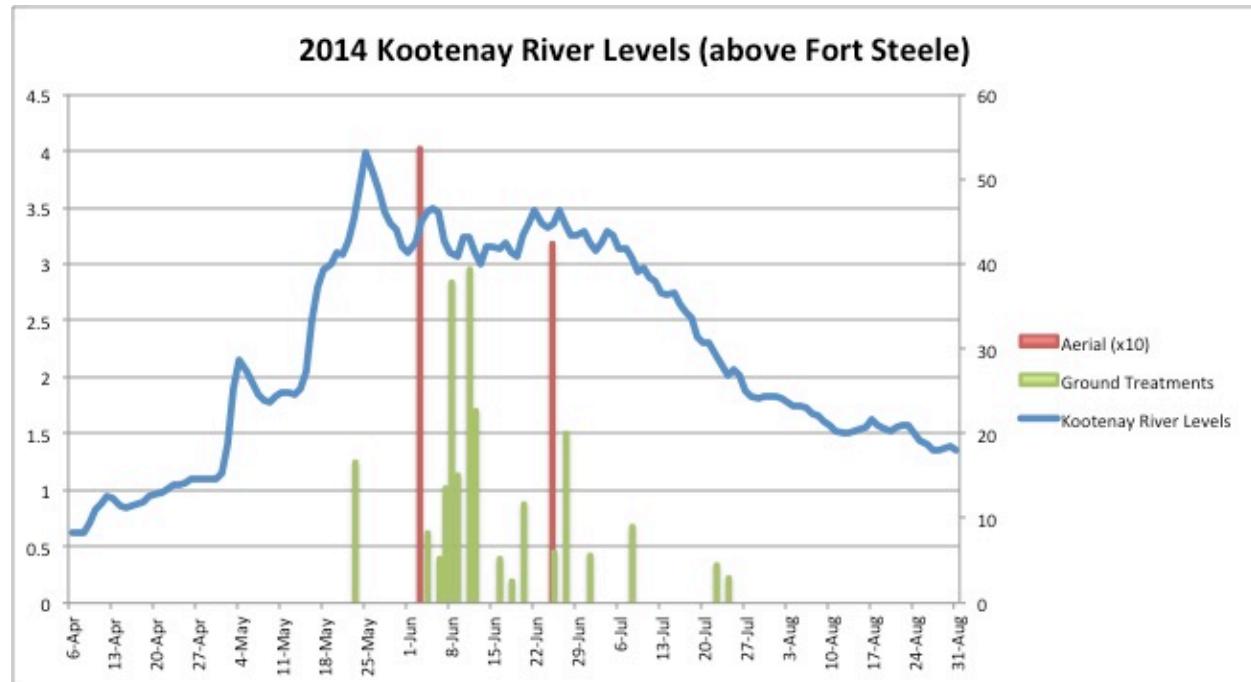

Figure 4 Note the increase in river level in early May. The green lines represent ground treatments and the red lines represent the one aerial (x10 to determine hectares treated).

MONITORING METHODOLOGY

The RDEK mosquito control program involves monitoring historically recognized mosquito development sites within the floodplain surrounding Wasa Lake, Tata Creek, and Skookumchuck. Although the monitoring area is relatively small, new sites are continually detected especially in high water years. High water means that the potential for seepage site development is also high. As there are numerous low-lying farms and benches throughout the floodplain, these areas are at a greater risk for the development of seepage from the Kootenay River. When new sites are found they are entered into a GIS database and monitored on the same schedule as are the historical sites.

In April and early May, the sites are visited at least once a week with the exception of the snowmelt-influenced sites, which are visited twice because they typically become active early. From mid-May through mid-August, each site is visited at least twice a week.

Aedes mosquitoes are the most common nuisance mosquitoes within the program. As opposed to other mosquitoes (i.e., *Culex*, *Culisetta*, *Anopholes*), *Aedes* lay their eggs on damp substrate in areas with a high flooding potential; they are often called ‘floodwater’ mosquitoes for this very reason. If the water flooding the eggs is sufficiently warm, contains a low enough dissolved oxygen (DO) content, and is organically rich (which contributes to a decreased DO content), hatching will commence (Gjullin et al. 1950).

The mosquito eggs hatch into larvae, which then go through 5 stages on their way to adulthood. The stages include 4 larval instars (or stages) and one pupal stage. These mosquitoes can hatch with densities recorded at levels up to 80 million per hectare, feeding many vertebrates and invertebrates for a few weeks each year before leaving the aquatic system.

Larval counts are made upon each visit and counts are distinguished between early instar (1st and 2nd) and late (3rd and 4th). Also at each visit, notes are made regarding pupae counts, which aid in distinguishing whether or not a treatment has been missed at a particular site. MBL treatment protocol dictates that field technicians target the late 3rd instar and early 4th instar stages in order to leave more biomass in the water for predators who depend on larvae as a food source.

LARVAL TREATMENT

Larval mosquitoes are treated with Aquabac®. Aquabac® is considered a microbial larvicide, meaning that the active ingredient is a soil-borne bacteria. In this case, the bacteria is *Bacillus thuringiensis* var. *israelensis* (Bti). The mode of action for Bti is relatively simple and with a rather high degree of species specificity. Receptors within the midgut region of the mosquito larvae are specific to the toxin proteins that are produced alongside each bacterial spore. After the mosquito larvae ingest the toxin protein, disruption of the larval midgut cells occurs as a result of cleavage of the protoxins by midgut proteases. An osmotic imbalance across the midgut epithelial cell membranes occurs due to this binding, which causes considerable damage to the wall of the gut and quickly leads to larval death (Boisvert and Boisvert, 2000). Bti has four specific endotoxins (Beaty and Marquardt, 1996).

Due to the specificity of the mosquito larval midgut receptors to the Bti endotoxins, Bti is a relatively safe treatment option. Besides mosquitoes, Bti also has an effect on black fly larvae. A commonly voiced concern is whether or not Bti has effects on salmonids. There is a large body of evidence that suggests Bti does not directly affect salmonids. Numerous studies have demonstrated the general safety of exposing fish to Bti (Brown et al. 1998, Brown et al. 2002, Brown et al. 2004). Hurst et al. (2007) subjected the crimson-spotted rainbowfish (*Melanotaenia duboulayi*) to 10 times the effective field concentration of Bs, Bti, and s-methoprene and reported no effects on their swimming performance. Sternberg et al. (2012) subjected juvenile coho salmon (*Oncorhynchus kisutch*) to the maximum recommended amount of a Bti product in two separate standard static toxicity tests (USEPA, 1996). No overt effects were observed on behavior or detected in fish weight. Therefore, amounts of Bti applied in field treatments are highly unlikely to cause direct hazard to juvenile salmonids.

MONITORING AND TREATMENT SUMMARY

Table 1 Each entry in the table indicates a monitoring and/or treatment event. In the event that there is no treatment indicated in column 5, then the event is considered a "monitoring only event".

SEASON TOTALS

Grand Total	QUANTITY APPLIED (kg)	AREA (ha)	APPLICATION MODE
	5,773.4	961.6	Aerial
	1,367.0	227.5	Blower/Hand
	7,140.4	1,189.1	

DISCUSSION

In an effort to assist all areas in broadcasting a uniform message regarding mosquito control and WNV, Morrow BioScience Ltd. operates a comprehensive website. This site can be found at www.morrowbioscience.com. MBL would encourage people to utilize this resource to help answer any questions they may have. MBL would also encourage the RDEK to provide a link to this website from their municipal site for easy access to local residents. It is planned to revamp/update the website prior to the 2015 season in order to further improve its content and presentation.

A total of 7,140.4kg of larvicide or approximately 392.3 bags (18.2kg/bag) were applied to 1,189.1ha during the season.

Plans for Mosquito Control Program Improvements – Future Seasons

- To effectively treat the service area we will need a higher budget/ more product.
- Start planning our budget based on a flood year. (By having more product available we will keep the inventory current by using the first in first out method).
- Continue to work with “Ducks unlimited” and “Natures Trust” on direction to be taken with “Bummers Flats”.
- Contact Parks Canada for trail upkeep around the lake
- Ensure we actively pursue the ongoing beaver dam problems
- Work on Thunderhoof culvert and dyke.
- Put culvert or dyke on north side of Thunderhoof

If you have any questions regarding this summary report, please do not hesitate to give me a call at 604-986-1168.
